METHODOLOGY

I. Overview

A cohort component II technique is used to project the 1980 population by age and sex for each of Tennessee's 95 counties to 1990 and 2000. The name of the technique implies the methodology. "Cohort" refers to specific age-sex groups (e.g., females 10-14 in 1980) that first are hypothetically aged 10 years to 1990, and second, aged 10 more years to 2000; "component" refers to the rates of fertility, mortality and migration assumed to be in effect over the projection period. To obtain the projected population, each age-sex group is increased or decreased by applying appropriate age-sex specific rates of fertility, mortality and net migration.

The components of change include observed fertility and mortality rates as well as estimated net migration rates for the initial population to be projected. Variations in the component rates provide the basis for a series of forecasts. Use of a projection series acknowledges the difficulty in predicting actual levels of future vital events and their cumulative effects in determining a future population size. Series projections provide a range of reasonable forecasts based upon variations in the component rates, they may be seen as responses to questions such as: "How large will our population be in 10 years <u>if</u> there are <u>no</u> changes in levels of births, deaths, or migration? In 20 years? If migration decreases? If fertility decreases?" Component rates thus become major assumptions in the projection process.

Schematically the procedure is:

A. Expected 1990 population = 1) Estimated births 1980-1990
2) Population 1980 X SR's

B. Net Migration estimates 1980-1990 = Expected 1990 population X NMR's

C. Population Projection 1990 = Expected 1990 population + Net migration estimate.

II. Steps in Making Population Projections

Population to be Projected

Each of Tennessee's 95 counties are projected from 1980 in 10 year increments to the years 1990 and 2000. Age-sex specific population counts were obtained from the 1980 census summary tape STFIB. The reported age distribution is in mixed age-intervals and required aggregation and interpolation to obtain the desired age distribution of: less than 1, 1-4, 5-9. . . 80-84, 85 and over. Simple addition was done where possible. The 10 year intervals required interpolation. The interpolation procedure involved several steps to obtain the final 5 year interval distribution. The reported 10 year intervals for ages 35-44, 45-64, and 55-64 were interpolated using Sprague multipliers for mixed 5 and 10 year age intervals. (U.S. Bureau of the Census, 1975, p. 876). As each target interval, beginning with 35-44, was interpolated, the 5 year age interval results were inserted in the age distribution to be used in interpolation of the next 10 year interval. The chain of calculations was applied through ages 55-64.

The 10 year age interval 65-74 was interpolated using Karup-King multipliers applied to the three 10-year age intervals, 55-64, 65-74 and 75-84. The interpolated values in 15 cases did not total to the original 10-year values due to rounding errors when interpolated values ended in 0.50. The "split individual" was added to the younger half of the interval to preserve original values (U.S. Bureau of the Census, 1975, p. 875).

The 75-84 age interval was interpolated in three steps. First, appropriate Sprague multipliers were used to obtain a set of two year

intervals. Second, Sprague multipliers were used to divide the interpolated 79-80 interval into first and second halves. Third, the appropriate 2 year and 1 year intervals were aggregated into the needed 5 year intervals (U.S. Bureau of the Census, 1975, p. 876). The use of interpolation procedures should not unduly distort the projections.

(B). Survival Rates-Overview

The mortality component was obtained by calculating life table forward survival rates (SR's). Age-sex specific life tables were constructed for each county for the years 1970 and 1980. State county registered age-sex specific deaths were used to create mortality rates which were transformed into proportions dying during an age interval (q_x). The set of q_x values was applied to a hypothetical cohort or life table radix of 100,000 births. The cohort was subjected to the mortality schedule, age by age until all members had died (e.g. 85 plus). The effects of mortality were then expressed in two ways (1) the number living in an age interval (L_x), and (2) the number living in one interval and all subsequent intervals (T_x). The L_x and T_x values were used to calculate 10 year survival rates. The 1970 SR's were used in calculating net migration rates used in the projection. 1980 SR's were used to express the mortality component under the assumption that there will be no change in the pattern of dying over the projection period.

SR's-1970-Data and Modifications

Census counts and vital events data for the State and each county were needed to construct the age and sex specific life tables for 1970. The 1970 population counts were obtained from the 1970 census (U.S. Bureau of the Census, 1973). Due to the undercount in the 1970 census, the census values were adjusted by inflating the age-sex specific

figures using adjustment factors provided by the U.S. Bureau of the Census (U.S. Bureau of the Census 1983, 1983a). For details on the adjustment procedure see Jacobsen and Hastings, 1983.

Total county births and state sex-specific birth data were obtained from the Tennessee vital statistics series for 1969, 1970 and 1971 (State of Tennessee Department of Public Health, 1969, 1970, 1971).

Total county deaths and state age-sex specific deaths were copied from the same Tennessee vital statistics series for the years 1969, 1970 and 1971. County total infant deaths and state sex-specific infant deaths were also obtained from these same volumes.

Given the volitility of infant mortality, slippage in coverage of vital events and the configuration of available data, several modifications to the original data were made.

1) Total births for each county, 1969, 1970, 1971 were proportioned into male and female births using a sex ratio at birth of 105 males to 100 females.

2) The sex proportioned births were census-centered using the formula:

B = .25 X Births 1969 + .50 X Births 1970 + .25 X Births 1971

Census-centered births were substituted for the census count in the under 1 age group.

3) County total deaths in 1969, 1970, 1971 were compared to the sum of state male and female state deaths in these years. The respective totals did not match. An adjustment was made, amounting to a total of 6 over the 3 years.

4) County total deaths were census-centered using the above weighted formula.

5) State age-specific deaths were reported in a mixed age distribution of 5 and 10 year intervals. The 10 year intervals were split by using the U.S. vital statistics data for Tennessee which reported information in greater age detail (U.S. Department of Health, Education and Welfare, 1973, 1974). The appropriate 5 year age figures reported in the U.S. vital statistics were substituted into the appropriate 10 year age group. In those instances where the 10 year intervals did not match, linear interpolations were calculated using the U.S. figures as a standard.

6) State age-sex specific deaths were census-centered using the same weighted formula as noted above.

7) County total deaths were proportioned into male and female deaths using the state sex-specific total deaths as a standard.

8) County male and female total deaths were indirectly standardized using the state age-sex specific death distribution. Proportions were obtained by dividing total sex specific deaths (less infant deaths) by deaths in each age-sex interval. The proportioning factors were then multiplied by county sex-specific total deaths. To retain the original county sex specific totals, rounding factors of .4997 for males and .5145 for females were used rather than .5.

9) Due to the small number of total deaths in some counties the standardization procedure returned 0.0 values of death in some age intervals, particularly in the ages 1-20. Since zero values could not be meaningfully used in calculating death rates a value of .01 was substituted. This substitution is

not large enough to introduce any error.

10) County total infant deaths were census-centered using the same weighted formula as above. The totals were then proportioned into male and female infant deaths using the state sex specific total infant deaths as a standard. The resulting figures were then substituted in the under 1 age group in the indirectly standardized death distribution.

SR's-1980-Data and Modifications

In addition to county and state age by sex population counts vital events data were required. Total births for each county and the state for the years 1979, 1980, and 1981 were obtained the State Data Center, Nashville. In the same manner as modifications made on the 1970 data, 1979, 1980 and 1981, total births were proportioned into male and female portions which were then census centered. The census centered births were substituted for the under one interval by sex in each county.

County and state death data for the years 1979, 1980, and 1981 were obtained from the State Data Center, Nashville. The 1979 and 1980 data were available for each county by age and sex. Total deaths by county were available for 1981. 1981 total deaths were modified in a manner similar to the 1970 death data. Total deaths were proportioned by sex using an average of the preceeding two year state totals by sex. The sex specific proportions for each county were then allocated into ages by averaging the preceding two years age-sex death distribution within each county. These distributions were

then used as a standard to distribute male and female deaths by age. Age and sex specific deaths were then census centered.

Infant deaths by sex for each county were obtained from the State Data Center, Nashville. Sex specific infant death were census centered and substituted for the under one interval in the appropraite death distributions by age and sex.

As in 1970, where an age interval showed zero deaths a value of .01 was substituted for computational reasons.

SR's - Procedure

The appropriate population count, births, and deaths were used to construct age-sex specific life tables for each county, 1970 and 1980. The age distribution for the life table is: 1, 1-4, 5-9 . . . 80-84, 85 and over.

L_x and T_x values from the life tables were used to calculate SR's. Except for the first two intervals and the last interval, SR's were obtained by dividing the L_x value for an age interval into the L_{x+10} age interval. For example:

$$SR_{10-14} = L_{20-24} / L_{0-14}$$

The first three L_x intervals in the life table are used to obtain SR's for those born during the 10 year survival period, or those 0-4 and 5-9 at the end of the period. The SR_{0-4} was obtained by adding the L_1 and L_{1-4} and dividing by the quantity 5 X 100,000 (Table Radix). The SR_{5-9} was obtained by dividing L_{5-9} by 500,000. The formulas are:

$$SR_{0-4} = L_1 + L_{1+4} / 5 * \text{Radix}$$

$$SR_{5-9} = L_{5-9} / 5 * \text{Radix}$$

The terminal SR for age group 75 and over was obtained by dividing the T_{75-79} by the T_{65-69} since T_x represents the persons living in the

interval and all subsequent intervals.

SR's are an essential component in the population projections. 1970 SR's are used in obtaining 10 year net-migration rates. 1980 SR's are the mortality component and are used to age the population 10 years to 1990 and again to 2000. Use of the 1980 SR's over the projection periods assumes there will be little change in the pattern of dying in the future. Increases or decreases in mortality are plausible from today's perspective due to the state of the economy and the apparent changes in government's social welfare role as seen in lower levels of federal spending on health care. Future improvements, however, will probably be slight and principally affect already low infant mortality and early childhood deaths and slightly lengthen an already long life expectancy.

C. Net Migration Rates

Net migration rates express the balance between in and out migration in each age category. NMR's are calculated for the 10 year period 1970-1980 using the forward survival technique. NMR's were calculated for the 1970 population and for those born during the decade. Inter-decade births are used to calculate NMR's for those who will be in the age intervals 0-4 and 5-9 in 1980.

In addition to the previously mentioned age-sex specific population counts for 1970 and 1980, the procedure required registered births for each county for each year of the decade 1970-1980. Birth data for the years 1970-1978 were obtained from the Tennessee vital statistic series (State of Tennessee Department of Public Health, 1970-1978). Birth data for the years 1979-1980 were obtained from the State Data Center in Nashville.

The census age distributions for 1970 and 1980 were modified by adding the under 1 and 1-4 intervals and aggregating the intervals 75-79, 80-84, and 85 plus. The age distribution thus becomes 0-4, 5-9, . . 70-74, 75 and over.

The birth data were grouped into two intervals, births April 1, 1970 - births April 1, 1975 and births April 1, 1975 - births April 1, 1980. The groupings were obtained by applying the following formulas:

Births 1970-1975=(.75* Births 1970)+(Births 1971, 1972, 1973, 1974) +(.25* Births 1975).

Births 1975-1980 =(.75 Births *1975) + (Births 1976, 1977, 1978, 1979) +(.25 * Births 1980).

After dividing births into two intervals they were proportioned into male and female births using a sex ratio at birth of 105:100 for each county.

Having obtained the necessary population data NMR's were calculated. The births and 1970 age distribution were subjected to the 1970-1980 SR's, thus obtaining an estimated age-sex population distribution for 1980. The estimated 1980 population was subtracted from the 1980 census population. The residual is the amount of net migration with the sign indicating whether the net migration was in (+) or out (-) for each age interval. NMR's were then calculated on a percentage basis by dividing the amount of net migration by the 1980 estimated population for each age interval. The sign of the NMR's is the sign of net estimate.

The general formula for 10 year NMR's is:

$$NMR_x = \frac{\text{Estimated Net Migration}_x}{\text{Estimated Population}_x} \times 100$$

Each county has an age-sex specific schedule of 10 year NMR's The age

distribution of the NMR's is: first half interdecade Births, second half interdecade Births, 0-4, 5-9, . . . 70-74, 75 and over.

Internal migration in the face of fairly stable mortality patterns and declining fertility has become a significant component in Tennessee's population change due to the rise of the Sunbelt. Tennessee has become an area of net in-migration. The migration component is thus the one most subject to change in the future. If the general status of economic activity improves in the coming decade, then net migration could remain at 1970-1980 levels or increase. If the economy remains stagnant or declines, net migration would be expected to decline. Three levels of net migration are used in the series to reflect the above assumptions about population movement. The calculated NMR's are taken as a middle range estimate; a 50% increase over present levels is taken as the high estimate; 50% decrease is taken as the low estimate.

The use of residual estimates of age-sex specific net migration does not take into account two aspects of population movement. First, international migration is not specifically considered. Tennessee is not a destination for large numbers of immigrants. Second, racial differences in net migration are not examined. Where race influences NMR's a separate series of projections may be warranted. However, such an effort is beyond the scope of this project.

D. Population Projections 1980 to 1990

The 10 year projection is performed in two steps. First, births are estimated during the projection decade to obtain counts for those who will be ages 0-4 and 5-9 in 1990. Birth projections are based upon county GFR's for 1980 and modified State GFR's 1980, 1980-1985 and 1985-

1990. The projected births are subjected to appropriate SR's and NMR's to obtain the final projected count. Second, the SR's and NMR's are applied to the 1980 population. Each age-sex specific cohort is aged 10 years by applying the 1980 10-year SR's to determine the surviving population in 1990. The projected population is then adjusted by applying 10-year NMR's and adding the signed estimate of net migration to the projected survivors. The 1980 age distribution is: Births 1980-1985, Births 1985-1990, 0-4, 5-9, . . .70-74, 75+.
The 1990 age distribution is: 0-4, 5-9 . . . 80-84, 85+.

Each projection series reflects different sets of component rate assumptions (See Table 2). For example: Series I uses the calculated SR's, NMR's and state GFR's. Each series begins with the same age by sex 1980 population count for each county.

One additional data set was obtained to make the 1990 projections. Total County births, 1981 were copied from material provided by the State Data Center (Tennessee Department of Public Health, 1982). Similar to other birth data, the totals were proportioned into male and female births. The first two intervals of the 1980 census population were aggregated to reflect the age distribution 0-4, 5-9 . . . 70-74, 75+. No other data or data modifications were necessary.

A critical component of the estimation procedure centers on estimating births which occur during the decade 1980-1990. The procedure followed may be found in Technical Paper 39, Guide for Local Area Projections (Bureau of Census, 1977a). Birth projections are derived by estimating 5-year county GFR's and applying them to estimates of the mid-5 year (1983 and 1988) female populations ages 15-44.

County general fertility ratios were obtained by calculating the ratio of 1980 county GFR's to the State 1980 GFR.

Projected county GFR's for each half of the decade were obtained by multiplying the 1980 GFR's against the estimated 5 year State projected GFR's. The female population 15-44 estimated for 1983 and 1988 was obtained through linear interpolation of the 1980 and 1990 projected female population ages 15-44. The projected county GFR's were then multiplied by the 1983 and 1988 estimates to obtain total births; since 5 year intervals were used, the result was multiplied by 5. Each half was then proportioned into male and females birth using the sex ratio of 105:100. The proportioned births were then multiplied by appropriate SR's and NMR's to obtain the projected counts for those ages 0-4 and 5-9 in 1990.

The projections for ages 10-14 . . . 80-84, 85+ were obtained by multiplying the 1980 population counts by their appropriate SR's. The effects of net migration were obtained by applying the NMR's to the expected or surviving 1990 population and adding the signed amount to the expected 1990 population. The projected intervals obtained in the 1st step, ages 0-4 and 5-9 are appended to the 10-14 . . . 80-84, 85+ projection obtained in the second step to yield the projected age distribution for 1990: 0-4, 5-9 . . . 80-84, 85+. Each projection series was obtained by varying one or more of the component rates. The component rates used in this series appear in Table 2. Variations in the net migration component were obtained by adjusting net migration a specified amount after applying the calculated NMR's; net migraton was specified to increase 50 percent or to decrease 50 percent. The various values of the component rates provides sets of assumptions for each projection series.

E. Projections 1990 to 2000

The year 2000 values were obtained by projecting the 1990 estimated population 10 years. The only procedural difference in the 2000 calculations was in determining the average number of births in 1990 used to compute county GFR's. 1990 average birth values were obtained by dividing the projected 1985-1990 total births by 5 for each county.

The series projections were then obtained by projecting interdecade births (1990 to 2000) to obtain values for those ages 0-4 and 5-9 in 2000, in the same manner as for 1990. The projections for those ages 10-14 and beyond in 2000 were obtained by applying SR's and NMR's for each series to the 1990 projected age distributions. The two sets of intervals were then joined to form the 2000 age distribution: 0-4, 5-9, . . . 80-84, 85+.

Given the volatility which can occur in migration and fertility, the 2000 projections are more tenuous than the 1990 projections. The farther the projected year is from the base year of projection and initial component rate calculations, the greater the caution that should be exercised in interpreting the forecasts.
